RFC 8913

Two-Way Active Measurement Protocol (TWAMP) YANG Data Model

Abstract

This document specifies a data model for client and server implementations of the Two-Way Active Measurement Protocol (TWAMP). This document defines the TWAMP data model through Unified Modeling Language (UML) class diagrams and formally specifies it using the YANG data modeling language (RFC 7950). The data model is compliant with the Network Management Datastore Architecture (NMDA).

Status of This Memo

This is an Internet Standards Track document.

This document is a product of the Internet Engineering Task Force (IETF). It represents the consensus of the IETF community. It has received public review and has been approved for publication by the Internet Engineering Steering Group (IESG). Further information on Internet Standards is available in Section 2 of RFC 7841.

Information about the current status of this document, any errata, and how to provide feedback on it may be obtained at <https://www.rfc-editor.org/info/rfc8913>.

1. Introduction

The [Two-Way Active Measurement Protocol \(TWAMP\)](#) [RFC5357] is used to measure network performance parameters such as latency, bandwidth, and packet loss by sending probe packets and measuring their experience in the network. To date, TWAMP implementations do not come with a standard management framework, and, as such, implementers have no choice except to provide a proprietary mechanism. This document addresses this gap by defining the model using Unified Modeling Language (UML) class diagrams [UML] and formally specifying a TWAMP data model that is compliant with the Network Management Datastore Architecture (NMDA) [RFC8342], using [YANG 1.1](#) [RFC7950].

1.1. Motivation

In current TWAMP deployments, the lack of a standardized data model limits the flexibility to dynamically instantiate TWAMP-based measurements across equipment from different vendors. In large, virtualized, and dynamically instantiated infrastructures where network functions are placed according to orchestration algorithms, proprietary mechanisms for managing TWAMP measurements pose severe limitations with respect to programmability.

Two major trends call for standardizing TWAMP management aspects. First, it is expected that in the coming years large-scale and multi-vendor TWAMP deployments will become the norm. From an operations perspective, using several vendor-specific TWAMP configuration mechanisms when one standard mechanism could provide an alternative is expensive and inefficient. Second, the increasingly software-defined and virtualized nature of network infrastructures, based on dynamic service chains [NSC] and programmable control and management planes [RFC7426],

requires a well-defined data model for TWAMP implementations. This document defines such a TWAMP data model and specifies it formally using the [YANG 1.1 data modeling language \[RFC7950\]](#).

1.2. Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [\[RFC2119\]](#) [\[RFC8174\]](#) when, and only when, they appear in all capitals, as shown here.

1.3. Document Organization

The rest of this document is organized as follows. [Section 2](#) presents the scope and applicability of this document. [Section 3](#) provides a high-level overview of the TWAMP data model. [Section 4](#) details the configuration parameters of the data model, and [Section 5](#) specifies in YANG the TWAMP data model. [Section 6](#) lists illustrative examples that conform to the YANG data model specified in this document. [Appendix A](#) elaborates these examples further.

2. Scope, Model, and Applicability

The purpose of this document is the specification of a vendor-independent data model for TWAMP implementations.

[Figure 1](#) illustrates a redrawn version of the TWAMP logical model found in [Section 1.2](#) of TWAMP [\[RFC5357\]](#). The figure is annotated with pointers to the [UML diagrams \[UML\]](#) provided in this document and associated with the data model of the four logical entities in a TWAMP deployment, namely the TWAMP Control-Client, Server, Session-Sender, and Session-Reflector. A UML Notation Guide is available in [Section 5](#) of UML [\[UML\]](#).

As per [TWAMP \[RFC5357\]](#), unlabeled links in [Figure 1](#) are left unspecified and may be proprietary protocols.

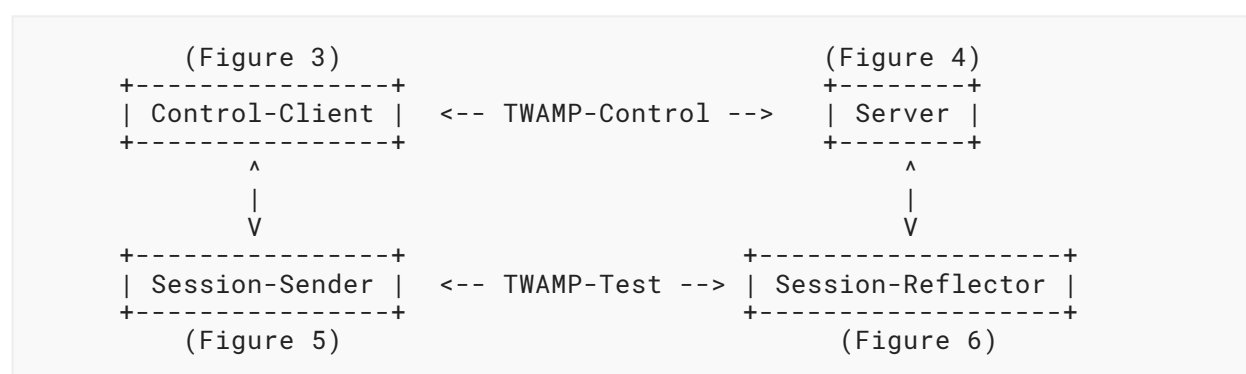

Figure 1: Annotated TWAMP Logical Model

As per [TWAMP \[RFC5357\]](#), a TWAMP implementation may follow a simplified logical model, in which the same node acts as both Control-Client and Session-Sender, while another node acts at the same time as both TWAMP Server and Session-Reflector. [Figure 2](#) illustrates this simplified logical model and indicates the interaction between the TWAMP configuration client and server using, for instance, [NETCONF \[RFC6241\]](#) or [RESTCONF \[RFC8040\]](#).

Figure 2: Simplified TWAMP Model and Protocols

The data model defined in this document is orthogonal to the specific protocol used between the Config client and Config server to communicate the TWAMP configuration parameters.

Operational actions such as how TWAMP-Test sessions are started and stopped, how performance measurement results are retrieved, or how stored results are cleared, and so on, are not addressed by the configuration model defined in this document. As noted above, such operational actions are not part of the TWAMP specification [\[RFC5357\]](#) and hence are out of scope for this document. See also [Appendix B](#). In addition, for operational state, the information provided in the Performance Metrics Registry [\[RFC8911\]](#) and [\[PERF-METRICS\]](#) can be used to develop an independent model for the Performance Metrics that need to be captured and retrieved.

3. Data Model Overview

The TWAMP data model includes four categories of configuration items.

First, global configuration items relate to parameters that are set on a per-device level. For example, the administrative status of the device with respect to whether it allows TWAMP sessions and, if so, in what capacity (e.g., Control-Client, Server, or both) is a typical instance of a global configuration item.

A second category includes attributes that can be configured on a per-TWAMP-Control-connection basis, such as the Server IP address.

A third category includes attributes related to per-TWAMP-Test-session attributes -- for instance, setting different values in the Differentiated Services Code Point (DSCP) field.

Finally, the data model includes attributes that relate to the operational state of the TWAMP implementation.

As the TWAMP data model is described in the remaining sections of this document, readers should keep in mind the functional entity grouping illustrated in [Figure 1](#).

3.1. Control-Client

A TWAMP Control-Client has an administrative status field set at the device level that indicates whether the node is enabled to function as such.

Each TWAMP Control-Client is associated with zero or more TWAMP-Control connections. The main configuration parameters of each control connection are:

- A name that can be used to uniquely identify at the Control-Client a particular control connection. This name is necessary for programmability reasons because at the time of creation of a TWAMP-Control connection not all IP and TCP port number information needed to uniquely identify the connection is available.
- The IP address of the interface the Control-Client will use for connections.
- The IP address of the remote TWAMP Server.
- Authentication and encryption attributes such as KeyID, Token, and the Control-Client Initialization Vector (Client-IV); see also Section 3.1 of "[A One-way Active Measurement Protocol \(OWAMP\)](#)" [RFC4656] and "[Randomness Requirements for Security](#)" [RFC4086].

Each TWAMP-Control connection, in turn, is associated with zero or more TWAMP-Test sessions. For each test session, the following configuration items should be noted:

- The test session name, which uniquely identifies a particular test session at the Control-Client and Session-Sender. Similar to the control connections mentioned above, this unique test session name is needed because at the time of creation of a TWAMP-Test session, for example, the source UDP port number is not known to uniquely identify the test session.
- The IP address and UDP port number of the Session-Sender on the path under test by TWAMP.
- The IP address and UDP port number of the Session-Reflector on said path.
- Information pertaining to the test packet stream, such as the test starting time; which Performance Metric is to be used, as defined in "[Registry for Performance Metrics](#)" [RFC8911]; or whether the test should be repeated.

3.2. Server

Each TWAMP Server has an administrative status field set at the device level to indicate whether the node is enabled to function as a TWAMP Server.

Each Server is associated with zero or more TWAMP-Control connections. Each control connection is uniquely identified by the 4-tuple {Control-Client IP address, Control-Client TCP port number, Server IP address, Server TCP port}. Control connection configuration items on a TWAMP Server are read-only.

3.3. Session-Sender

A TWAMP Session-Sender has an administrative status field set at the device level that indicates whether the node is enabled to function as such.

There is one Session-Sender instance for each TWAMP-Test session that is initiated from the sending device. Primary configuration fields include:

- The test session name, which **MUST** be identical to the corresponding test session name on the TWAMP Control-Client ([Section 3.1](#)).
- The control connection name, which, along with the test session name, uniquely identifies the TWAMP Session-Sender instance.
- Information pertaining to the test packet stream, such as the number of test packets and the packet distribution to be employed; see also "[Network performance measurement with periodic streams](#)" [[RFC3432](#)].

3.4. Session-Reflector

Each TWAMP Session-Reflector has an administrative status field set at the device level to indicate whether the node is enabled to function as such.

Each Session-Reflector is associated with zero or more TWAMP-Test sessions. For each test session, the REFWAIT timeout parameter, which determines whether to discontinue the session if no packets have been received (TWAMP [[RFC5357](#)], [Section 4.2](#)), can be configured.

Read-only access to other data model parameters, such as the Sender IP address, is foreseen. Each test session can be uniquely identified by the 4-tuple mentioned in [Section 3.2](#).

4. Data Model Parameters

This section defines the TWAMP data model using UML [[UML](#)] and introduces selected parameters associated with the four TWAMP logical entities. The complete TWAMP data model specification is provided in the YANG module presented in [Section 5.2](#).

4.1. Control-Client

The client container (see [Figure 3](#)) holds items that are related to the configuration of the TWAMP Control-Client logical entity (recall [Figure 1](#)).

The client container includes an administrative configuration parameter (client/admin-state) that indicates whether the device is allowed to initiate TWAMP-Control connections.

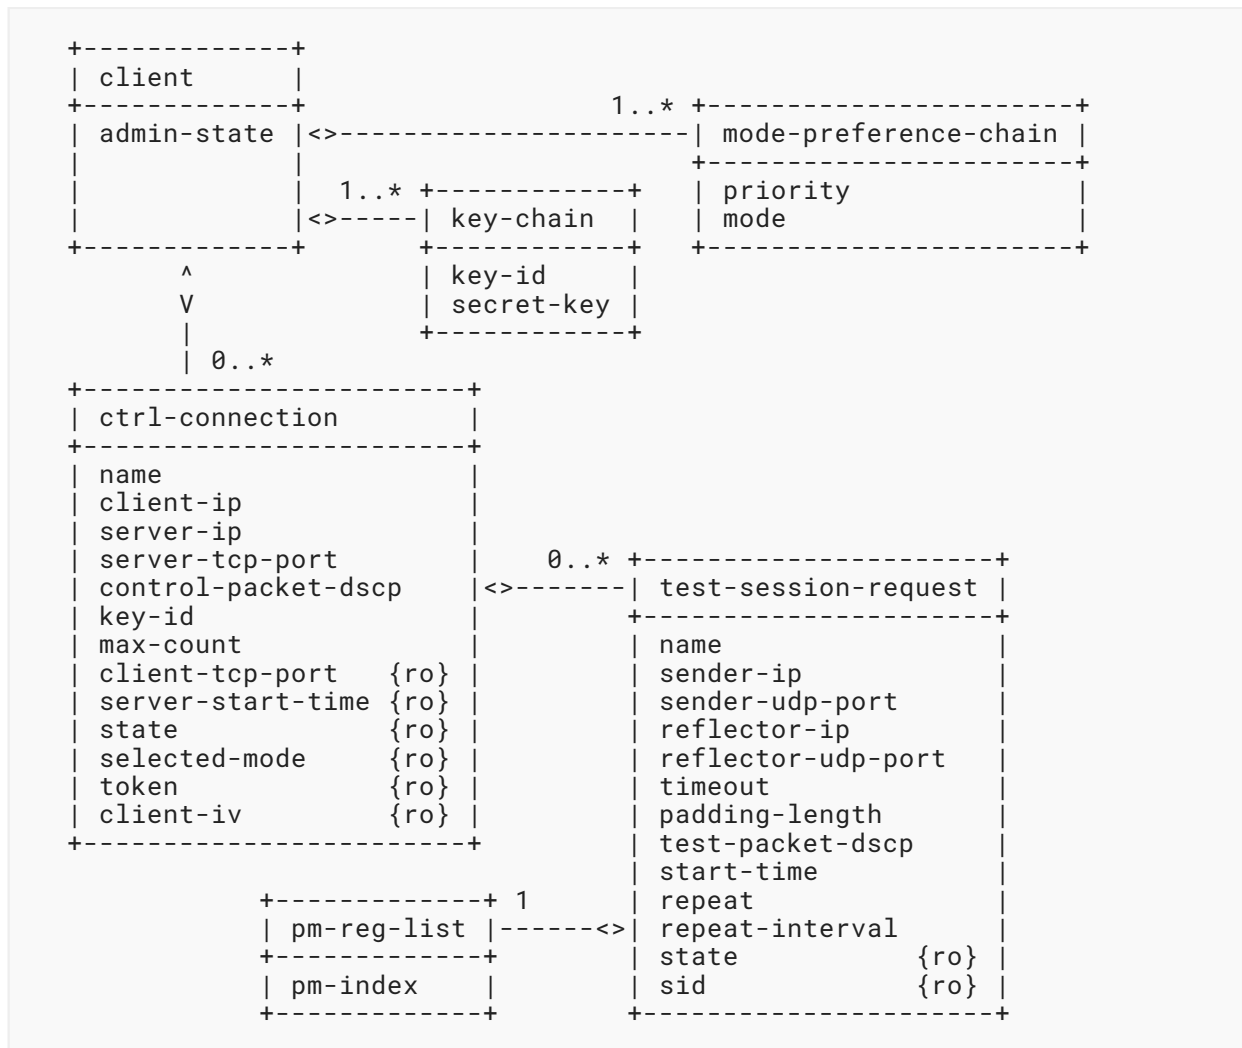

Figure 3: TWAMP Control-Client UML Class Diagram

The client container holds a list (mode-preference-chain) that specifies the mode values according to their preferred order of use by the operator of this Control-Client, including the authentication and encryption modes. Specifically, mode-preference-chain lists the mode and its corresponding priority, expressed as a 16-bit unsigned integer. Values for the priority start with zero, the highest priority, and decreasing priority value is indicated by every increase in value by one.

Depending on the modes available in the Server Greeting, the Control-Client **MUST** choose the highest-priority mode from the configured mode-preference-chain list.

Note that the list of preferred modes may set multiple bit positions independently, such as when referring to the extended TWAMP features in "[Mixed Security Mode for the Two-Way Active Measurement Protocol \(TWAMP\)](#)" [RFC5618], "[Individual Session Control Feature for the Two-Way Active Measurement Protocol \(TWAMP\)](#)" [RFC5938], "[Two-Way Active Measurement Protocol \(TWAMP\) Reflect Octets and Symmetrical Size Features](#)" [RFC6038], and "[IKEv2-Derived Shared](#)

[Secret Key for the One-Way Active Measurement Protocol \(OWAMP\) and Two-Way Active Measurement Protocol \(TWAMP\)](#) [RFC7717]. If the Control-Client cannot determine an acceptable mode, or when the bit combinations do not make sense, e.g., authenticated and unauthenticated bits are both set, it **MUST** respond with zero Mode bits set in the Set-Up-Response message, indicating that it will not continue with the control connection.

In addition, the client container holds a list named "key-chain", which relates key-id with the respective secret-key. Both the Server and the Control-Client use the same mappings from key-id to secret-key (in [Figure 3](#)); in order for this to work properly, key-id must be unique across all systems in the administrative domain. The Server, being prepared to conduct sessions with more than one Control-Client, uses key-id to choose the appropriate secret-key; a Control-Client would typically have different secret keys for different Servers. The secret-key is the shared secret, of type "binary", and the length **SHOULD** contain at least 128 bits of entropy. The key-id and secret-key encoding **SHOULD** follow [Section 9.8](#) of YANG [RFC7950]. The derived key length (dkLen as defined in "PKCS #5: Password-Based Cryptography Specification Version 2.1" [RFC8018]) **MUST** be 16 octets for the AES Session-key used for encryption and 32 octets for the HMAC-SHA1 Session-key used for authentication; see also [Section 6.10](#) of OWAMP [RFC4656].

Each client container also holds a list of control connections, where each item in the list describes a TWAMP-Control connection initiated by this Control-Client. There **SHALL** be one ctrl-connection per TWAMP-Control (TCP) connection that is to be initiated from this device.

In turn, each ctrl-connection holds a test-session-request list. Each test-session-request holds information associated with the Control-Client for this test session. This includes information associated with the Request-TW-Session/Accept-Session message exchange (see [Section 3.5](#) of TWAMP [RFC5357]).

There **SHALL** be one instance of test-session-request for each TWAMP-Test session that is to be negotiated by this TWAMP-Control connection via a Request-TW-Session/Accept-Session exchange.

The Control-Client is also responsible for scheduling TWAMP-Test sessions; therefore, test-session-request holds information related to these actions (e.g., pm-index, repeat-interval).

4.2. Server

The server container (see [Figure 4](#)) holds items that are related to the configuration of the TWAMP Server logical entity (recall [Figure 1](#)).

The server container includes an administrative configuration parameter (server/admin-state) that indicates whether the device is allowed to receive TWAMP-Control connections.

A device operating in the Server Role cannot configure attributes on a per-TWAMP-Control-connection basis, as it has no foreknowledge of the incoming TWAMP-Control connections to be received. Consequently, any parameter that the Server might want to apply to an incoming control connection must be configured at the overall Server level and applied to all incoming TWAMP-Control connections.

Figure 4: TWAMP Server UML Class Diagram

Each server container holds a list named "key-chain", which relates key-id with the respective secret-key. As mentioned in [Section 4.1](#), both the Server and the Control-Client use the same mapping from key-id to the shared secret-key; in order for this to work properly, key-id must be unique across all the systems in the administrative domain. The Server, being prepared to conduct sessions with more than one Control-Client, uses key-id to choose the appropriate secret-key; a Control-Client would typically have different secret keys for different Servers. key-id tells the Server which shared secret-key the Control-Client wishes to use for authentication or encryption.

Each incoming control connection active on the Server is represented by a ctrl-connection. There **SHALL** be one ctrl-connection per incoming TWAMP-Control (TCP) connection that is received and active on the Server. Each ctrl-connection can be uniquely identified by the 4-tuple {client-ip, client-tcp-port, server-ip, server-tcp-port}. All items in the ctrl-connection list are read-only.

4.3. Session-Sender

The session-sender container, illustrated in [Figure 5](#), holds items that are related to the configuration of the TWAMP Session-Sender logical entity.

The session-sender container includes an administrative parameter (session-sender/admin-state) that controls whether the device is allowed to initiate TWAMP-Test sessions.

Figure 5: TWAMP Session-Sender UML Class Diagram

Each TWAMP-Test session initiated by the Session-Sender will be represented by an instance of a test-session object. There **SHALL** be one instance of test-session for each TWAMP-Test session for which packets are being sent.

4.4. Session-Reflector

The session-reflector container, illustrated in [Figure 6](#), holds items that are related to the configuration of the TWAMP Session-Reflector logical entity.

The session-reflector container includes an administrative parameter (session-reflector/admin-state) that controls whether the device is allowed to respond to incoming TWAMP-Test sessions.

A device operating in the Session-Reflector Role cannot configure attributes on a per-session basis, as it has no foreknowledge of what incoming sessions it will receive. As such, any parameter that the Session-Reflector might want to apply to an incoming TWAMP-Test session must be configured at the overall Session-Reflector level and applied to all incoming sessions.

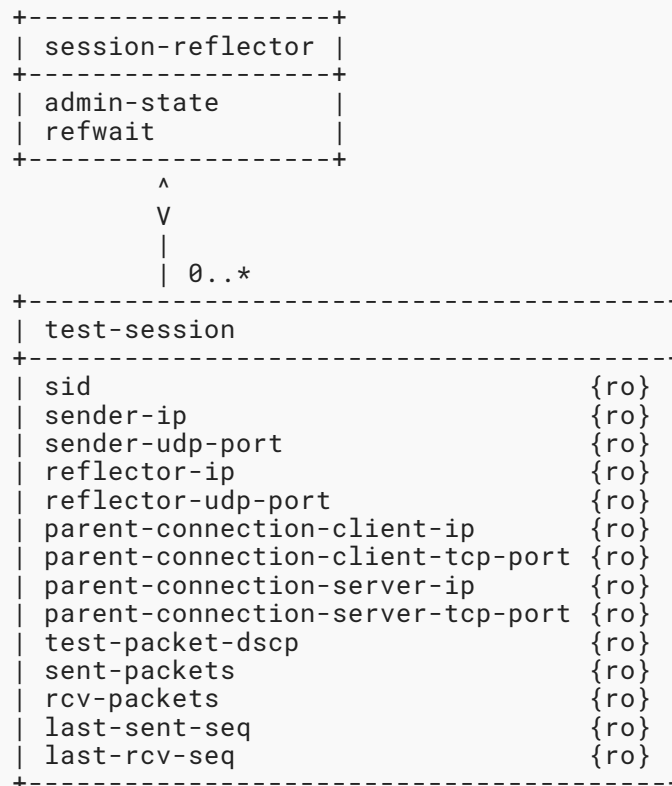

Figure 6: TWAMP Session-Reflector UML Class Diagram

Each incoming TWAMP-Test session that is active on the Session-Reflector **SHALL** be represented by an instance of a test-session object. All items in the test-session object are read-only.

Instances of test-session are indexed by a Session Identifier (SID) (the sid parameter). This SID value is auto-allocated by the TWAMP Server as test session requests are received and is communicated back to the Control-Client in the SID field of the Accept-Session message; see Section 4.3 of "[Two-Way Active Measurement Protocol \(TWAMP\) Reflect Octets and Symmetrical Size Features](#)" [RFC6038].

When attempting to retrieve operational data for active test sessions from a Session-Reflector device, the user will not know what sessions are currently active on that device or what SIDs have been auto-allocated for these test sessions. If the user has network access to the Control-Client device, then it is possible to read the data for this session under client/ctrl-connection/test-session-request/sid and obtain the SID (see [Figure 3](#)). The user may then use this SID value as an index to retrieve an individual session-reflector/test-session instance on the Session-Reflector device.

If the user has no network access to the Control-Client device, then the only option is to retrieve all test-session instances from the Session-Reflector device and then pick out specific test-session instances of interest to the user. This could be problematic if a large number of test sessions are currently active on that device.

Each Session-Reflector TWAMP-Test session contains the following 4-tuple: {parent-connection-client-ip, parent-connection-client-tcp-port, parent-connection-server-ip, parent-connection-server-tcp-port}. This 4-tuple **MUST** correspond to the equivalent 4-tuple {client-ip, client-tcp-port, server-ip, server-tcp-port} in server/ctrl-connection. This 4-tuple allows the user to trace back from the TWAMP-Test session to the (parent) TWAMP-Control connection that negotiated this test session.

5. Data Model

This section formally specifies the TWAMP data model using YANG.

5.1. YANG Tree Diagram

This section presents a simplified graphical representation of the TWAMP data model using a YANG tree diagram. Readers should keep in mind that the limit of 72 characters per line forces us to introduce artificial line breaks in some tree diagram nodes. Tree diagrams used in this document follow the notation defined in "[YANG Tree Diagrams](#)" [RFC8340].

Please note that the backslash ('\') character near the end of the diagram is used for formatting purposes only (i.e., "reflector-udp-port]" should be treated as part of the same line as "[sender-ip sender-udp-port reflector-ip").

Figure 7: YANG Tree Diagram

5.2. YANG Module

This section presents the YANG module for the TWAMP data model defined in this document. The module imports definitions from ["Common YANG Data Types" \[RFC6991\]](#) and references ["Framework for IP Performance Metrics" \[RFC2330\]](#), ["Network performance measurement with periodic streams" \[RFC3432\]](#), ["A One-way Active Measurement Protocol \(OWAMP\)" \[RFC4656\]](#), ["A Two-Way Active Measurement Protocol \(TWAMP\)" \[RFC5357\]](#), ["Mixed Security Mode for the Two-Way Active Measurement Protocol \(TWAMP\)" \[RFC5618\]](#), ["Network Time Protocol Version 4: Protocol and Algorithms Specification" \[RFC5905\]](#), ["Individual Session Control Feature for the Two-Way Active Measurement Protocol \(TWAMP\)" \[RFC5938\]](#), ["Two-Way Active Measurement Protocol \(TWAMP\) Reflect Octets and Symmetrical Size Features" \[RFC6038\]](#), ["Advanced Stream and Sampling Framework for IP Performance Metrics \(IPPM\)" \[RFC7312\]](#), ["IKEv2-Derived Shared Secret Key for the One-Way Active Measurement Protocol \(OWAMP\) and Two-Way Active Measurement Protocol \(TWAMP\)" \[RFC7717\]](#), ["Well-Known Port Assignments for the One-Way Active Measurement Protocol \(OWAMP\) and the Two-Way Active Measurement Protocol \(TWAMP\)" \[RFC8545\]](#), and ["Registry for Performance Metrics" \[RFC8911\]](#).

  description
    "This YANG module specifies a vendor-independent data
    model for the Two-Way Active Measurement Protocol (TWAMP).

    The data model defines four TWAMP logical entities, namely
    Control-Client, Server, Session-Sender, and Session-Reflector,
    as illustrated in the annotated TWAMP logical model (Figure 1
    of RFC 8913).

    This YANG module uses features to indicate which of the four
    logical entities are supported by a TWAMP implementation.

    The key words 'MUST', 'MUST NOT', 'REQUIRED', 'SHALL', 'SHALL
    NOT', 'SHOULD', 'SHOULD NOT', 'RECOMMENDED', 'NOT RECOMMENDED',
    'MAY', and 'OPTIONAL' in this document are to be interpreted as
    described in BCP 14 (RFC 2119) (RFC 8174) when, and only when,
    they appear in all capitals, as shown here.

      the Server Greeting message and used for deriving a key
      from a shared secret as per Section 3.1 of RFC 4656:
      MUST be a power of 2 and at least 1024. It is configured
      by providing said power. For example, configuring 20 here
      means count  $2^{20} = 1048576$ . The default is 15,
      meaning  $2^{15} = 32768$ .";
  }
}
```

```

    }
    description
      "Reusable data structure for count, which is used in both the
      Server and the Control-Client.";
  }

  grouping max-count-exponent {
    leaf max-count-exponent {
      type uint8 {
        range "10..31";
      }
      default "20";
      description
        "This parameter limits the maximum Count value, which MUST
        be a power of 2 and at least 1024 as per RFC 5357. It is
        configured by providing said power. For example,
        configuring 10 here means max count  $2^{10} = 1024$ .
        The default is 20, meaning  $2^{20} = 1048576$ .

        A TWAMP Server uses this configured value in the
        Server Greeting message sent to the Control-Client.

        A TWAMP Control-Client uses this configured value to
        prevent denial-of-service (DoS) attacks by closing the
        control connection to the Server if it 'receives a
        Server-Greeting message with Count greater than [sic] its
        maximum configured value', as per Section 6 of RFC 5357.

        Further, note that according to Section 6 of RFC 5357:

        'If an attacking system set the maximum value in Count
        ( $2^{32}$ ), then the system under attack would stall for a
        significant period of time while it attempts to generate
        keys. Therefore, TWAMP-compliant systems SHOULD have a
        configuration control to limit the maximum Count value.
        The default maximum Count value SHOULD be 32768.'

        In the case of this document, the default max-count-exponent
        value SHOULD be 15, which corresponds to a maximum value of
         $2^{15}$  or 32768.

        RFC 5357 does not qualify 'significant period' in terms of
        time, but it is clear that this depends on the processing
        capacity available, and operators need to pay attention to
        this security consideration.";
    }

6. Data Model Examples

This section presents simple but complete examples of configuring all four entities in [Figure 1](#), based on the YANG module specified in [Section 5](#). The examples are illustrative in nature but aim to be self-contained, i.e., were they to be executed in a real TWAMP implementation, they would lead to correctly configured test sessions. For completeness, examples are provided for both IPv4 and IPv6. The examples are shown using XML [[W3C.REC-xml-20081126](#)].

More elaborate examples, which also include authentication parameters, are provided in [Appendix A](#).

6.1. Control-Client

[Figure 8](#) shows a configuration example for a Control-Client with client/admin-state enabled. In a real implementation following [Figure 2](#), this would permit the initiation of TWAMP-Control connections and TWAMP-Test sessions.

```
<?xml version="1.0" encoding="utf-8"?>
<config xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <twamp xmlns="urn:ietf:params:xml:ns:yang:ietf-twamp">
    <client>
      <admin-state>true</admin-state>
    </client>
  </twamp>
</config>
```

Figure 8: XML Instance Enabling Control-Client Operation

The following example shows a Control-Client with two instances of client/ctrl-connection -- one called "RouterA" and another called "RouterB". Each TWAMP-Control connection is to a different Server. The control connection named "RouterA" has two test session requests. The TWAMP-Control connection named "RouterB" has no TWAMP-Test session requests.

```

6.2. Server

Figure 9 shows a configuration example for a Server with server/admin-state enabled, which permits a device following Figure 2 to respond to TWAMP-Control connections and TWAMP-Test sessions.

```

<?xml version="1.0" encoding="utf-8"?>
<config xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <twamp xmlns="urn:ietf:params:xml:ns:yang:ietf-twamp">
    <server>
      <admin-state>true</admin-state>
    </server>
  </twamp>
</config>

```

Figure 9: XML Instance Enabling Server Operation

The following example presents a Server with the TWAMP-Control connection corresponding to the control connection name (client/ctrl-connection/name) "RouterA" presented in [Section 6.1](#).

```
<?xml version="1.0" encoding="utf-8"?>
<data xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <twamp xmlns="urn:ietf:params:xml:ns:yang:ietf-twamp">
    <server>
      <admin-state>true</admin-state>
      <ctrl-connection>
        <client-ip>203.0.113.1</client-ip>
        <client-tcp-port>16341</client-tcp-port>
        <server-ip>203.0.113.2</server-ip>
        <server-tcp-port>862</server-tcp-port>
        <state>active</state>
      </ctrl-connection>
    </server>
  </twamp>
</data>
```

```
<?xml version="1.0" encoding="utf-8"?>
<data xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <twamp xmlns="urn:ietf:params:xml:ns:yang:ietf-twamp">
    <server>
      <admin-state>true</admin-state>
      <ctrl-connection>
        <client-ip>2001:db8:203:0:113::1</client-ip>
        <client-tcp-port>16341</client-tcp-port>
        <server-ip>2001:db8:203:0:113::2</server-ip>
        <server-tcp-port>862</server-tcp-port>
        <state>active</state>
      </ctrl-connection>
    </server>
  </twamp>
</data>
```

6.3. Session-Sender

[Figure 10](#) shows a configuration example for a Session-Sender with session-sender/admin-state enabled, which permits a device following [Figure 2](#) to initiate TWAMP-Test sessions.

```
<?xml version="1.0" encoding="utf-8"?>
<config xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <twamp xmlns="urn:ietf:params:xml:ns:yang:ietf-twamp">
    <session-sender>
      <admin-state>true</admin-state>
    </session-sender>
  </twamp>
</config>
```

Figure 10: XML Instance Enabling Session-Sender Operation

The following configuration example shows a Session-Sender with the two TWAMP-Test sessions presented in [Section 6.1](#).

```
<?xml version="1.0" encoding="utf-8"?>
<data xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <twamp xmlns="urn:ietf:params:xml:ns:yang:ietf-twamp">
    <session-sender>
      <admin-state>true</admin-state>
      <test-session>
        <name>Test1</name>
        <ctrl-connection-name>RouterA</ctrl-connection-name>
        <number-of-packets>900</number-of-packets>
        <periodic-interval>1</periodic-interval>
      </test-session>
      <test-session>
        <name>Test2</name>
        <ctrl-connection-name>RouterA</ctrl-connection-name>
        <number-of-packets>900</number-of-packets>
        <lambda>1</lambda>
        <max-interval>2</max-interval>
      </test-session>
    </session-sender>
  </twamp>
</data>
```

6.4. Session-Reflector

This configuration example shows a Session-Reflector with session-reflector/admin-state enabled, which permits a device following [Figure 2](#) to respond to TWAMP-Test sessions.

```
<?xml version="1.0" encoding="utf-8"?>
<config xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <twamp xmlns="urn:ietf:params:xml:ns:yang:ietf-twamp">
    <session-reflector>
      <admin-state>true</admin-state>
    </session-reflector>
  </twamp>
</config>
```

Figure 11: XML Instance Enabling Session-Reflector Operation

The following example shows the two Session-Reflector TWAMP-Test sessions corresponding to the test sessions presented in [Section 6.3](#).

7. Security Considerations

Virtually all existing measurement systems using [TWAMP \[RFC5357\]](#) are administered by the same network operator. For example, attacks on the measurement infrastructure could be launched by third parties to commandeer the packet generation capability, corrupt the measurements, or perform other nefarious acts.

The YANG module specified in this document defines a schema for data that is designed to be accessed via network management protocols such as [NETCONF \[RFC6241\]](#) or [RESTCONF \[RFC8040\]](#). The lowest NETCONF layer is the secure transport layer, and the mandatory-to-implement secure transport is [Secure Shell \(SSH\) \[RFC6242\]](#). The lowest RESTCONF layer is HTTPS, and the mandatory-to-implement secure transport is [TLS \[RFC8446\]](#).

The [Network Configuration Access Control Model \(NACM\) \[RFC8341\]](#) provides the means to restrict access for particular NETCONF or RESTCONF users to a preconfigured subset of all available NETCONF or RESTCONF protocol operations and content.

There are a number of data nodes defined in this YANG module that are writable/creatable/deletable (i.e., config true, which is the default). These data nodes may be considered sensitive or vulnerable in some network environments. Write operations (e.g., edit-config) to these data nodes without proper protection can have a negative effect on network operations. These are the subtrees and data nodes and their sensitivity/vulnerability:

- If written, the 'admin-state' node can cause unintended test sessions to be created.
- If the node 'number-of-packets', which dictates how many packets are sent in any particular test session, is written with a large value, it can cause a test session to run longer than expected.
- Nodes that are particularly vulnerable include several timeout values put in the protocol to protect against sessions that are not active but are consuming resources. These are the REFWAIT timeout parameter, which determines whether to discontinue the session if no packets are received; and the nodes 'count' and 'max-count-exponent', which can cause a long time to be spent on Password-Based Key Derivation Function 2 (PBKDF2) iterations.
- In addition, a 'dscp' node marked with different DSCP markings can cause the test traffic on the network to be skewed and the result manipulated.
- Finally, nodes within 'mode-preference-chain', which specifies the 'mode' and 'priority' values and indicates the preferred order of use by an operator, can be manipulated to send unauthenticated or non-encrypted traffic, enabling an on-path attack.
- Limiting access to these nodes will limit the ability to launch an attack in network environments.

Some of the readable data nodes in this YANG module may be considered sensitive or vulnerable in some network environments. It is thus important to control read access (e.g., via get, get-config, or notification) to these data nodes. This is the subtree and data node and its sensitivity/vulnerability:

- The 'token' node defined in the model, containing a concatenation of a Challenge, an AES Session-key used for encryption, and an HMAC-SHA1 Session-key used for authentication, is sensitive from a privacy perspective and can be used to disrupt a test session. The ability to read the field should be limited to the administrator of the test network.

The TWAMP YANG data model does not define RPC operations, as detailed in [Appendix B](#), and defers the definition of NETCONF RPC operations to each implementation. These RPC operations, when defined, may be considered sensitive or vulnerable in some network environments. It is thus important to control access to these operations.

8. IANA Considerations

IANA has registered the following URI in the "IETF XML Registry" [[RFC3688](#)].

URI: urn:ietf:params:xml:ns:yang:ietf-twamp
Registrant Contact: The IESG.
XML: N/A; the requested URI is an XML namespace.

IANA has registered the following YANG module in the "YANG Module Names" registry [[RFC6020](#)].

Name: ietf-twamp
Namespace: urn:ietf:params:xml:ns:yang:ietf-twamp
Prefix: twamp
Reference: RFC 8913

Appendix A. Detailed Data Model Examples

This appendix extends the examples presented in [Section 6](#) by configuring more fields, such as authentication parameters, DSCP values, and so on.

A.1. Control-Client

```

Appendix B. TWAMP Operational Commands

TWAMP operational commands could be performed programmatically or manually, e.g., using a command-line interface (CLI).

With respect to programmability, YANG can be used to define NETCONF Remote Procedure Calls (RPCs); therefore, it would be, in principle, possible to define TWAMP RPC operations for actions such as starting or stopping control connections, test sessions, or groups of sessions; retrieving results; clearing stored results; and so on.

However, [TWAMP \[RFC5357\]](#) does not attempt to describe such operational actions. Refer also to [Section 2](#) and the unlabeled links in [Figure 1](#). In actual deployments, different TWAMP implementations may support different sets of operational commands, with different restrictions. Therefore, this document considers it the responsibility of the individual implementation to define its corresponding data model for TWAMP operational commands.

Acknowledgments

We thank Fred Baker, Kevin D'Souza, Gregory Mirsky, Brian Trammell, Robert Sherman, and Marius Georgescu for their thorough and constructive reviews, comments, and text suggestions.

Haoxing Shen contributed to the definition of the YANG module in [Section 5](#).

Jan Lindblad and Ladislav Lhotka did thorough reviews of the YANG module and the examples in [Appendix A](#).
